

GUI coding is the more basic surface level of coding. It is very user friendly and probably everyone who has ever used a computer before has done some form of GUI coding because it is what is most often used for things like creating and adding folders to your desktop. It is also often used in search engines like when you are doing something in a document and you find an image you want to use, if you drag and drop that image into your document you just used GUI coding. GUI is easier to understand but once you get more advanced it can be slow and clunky.

CLI gets more in depth and starts looking into the inner workings of code, it is text based rather than just clicking and choosing from a list of options. When you use CLI you manually input the prompt. You can do all the same things that people use GUI for with CLI and once you gain understanding with it, it is often quicker and more precise than GUI. CLI is also easier to connect to a variety of other programs whereas GUI cannot usually interact across other sources.
